Intro

Some "Best Practices" for Research*

- 1. Everything starts with a question
- 2. Theory comes first, data next, modeling decisions last
- 3. Learn to listen to your data
- 4. Don't model data you don't understand
- 5. Good visualizations are always better
- 6. Tell a story

Data Types I

- The most basic way to differentiate types of data is to ask: what is it that we are describing?
- Discrete data: things you can count
 - All values are integers
 - These are often counts or categories of things
- Continuous data: things you can measure
 - Values can be fractions of a number
 - These are generally measurements of things

- We can also talk about different types of variables
 - As with discrete vs continuous data, we are still agnostic to things like software at this level of discussion
- Four types of variables:
 - 1. Nominal
 - 2. Ordinal
 - 3. Interval
 - 4. Ratio

Data Types III: R

- In R, there are six data types:
 - character
 - 2. numeric
 - integer
 - logical
 - 5. complex
 - 6. raw
- Note: the relationship between variable types and R data types is not as clear as one might like. This can (and likely will) cause you headaches at times. However, understanding both is vital when working with quant data in R.

Data Basics 00000000

Identifying Data Types in R: Core Functions

There are several core functions to use with data types

```
### DATA TYPES AND STRUCTURES ----
# Core functions to determine data type
class()
typeof()
str()
# Functions to convert data types
as.numeric()
as.integer()
as.character()
# Core functions to determine any object's class
is.numeric()
is.integer()
is.numeric()
is.na()
```

```
of these data types will not be something we'll use (like complex and raw)
00 00 00 00 00
```

```
Character
    <- "apple"
 class(x)
[1] "character"
> str(x) # prints class and content of the object
chr "apple"
 # Using double quote marks, 4 becomes a character
 z <- c("apple", "4")
> str(z)
chr [1:2] "apple" "4"
```

Identifying Data Types in R: Numeric, Integer, Double

```
When R stores a number in a variable, it converts the number into a "double" value or a decimal type with at least two decimal places. This means that a
                         "1" here, is stored as 1.00 with a type of double and a
      Double is a real number stored in "double-precision floating point format."
     "double"
    "numeric"
     the L tells R to store this as an integer. Many R programmers do not use this mode since every integer value can be represented as a double. An integer can be positive or negative.
   # You can convert numeric to integer
 my num int <- as.integer(my num)
  class(mv num int)
[1] "integer"
 # You can even convert numeric to character
my_num_character <- as.character(my_num)
str(my_num_character)</pre>
chr [1:4] "5" "6" "7 1" "8 7"
```

```
[1] "logical"
 logi [1:4] FALSE FALSE TRUE TRUE
[1] TRUE
   "logical"
[1] TRUE
 str(mv logical2)
 logi [1:4] FALSE FALSE TRUE TRUE
     ere, I have numbers in my vector, and R will force it to numeric class
```

Goals of Descriptive Statistics

- Simplifying data samples by describing key attributes
- Reading meaningful information out of large lists
- Providing data for use in inference about the population
- Key descriptives focus on measures of center, range, distribution of data

- As we will see this semester, many of the estimators we use depend upon assumptions about variable types, their distributions, their relationships with each other, etc
- Descriptive stats offer a quick look at individual variables (or sets of variables) to reveal important information
- This can also save us from making major errors when dealing with "canned" data

Key R Commands

```
• • •
# Basic functions to use for descriptives ----
summary() # produces result summaries
mean() # arithmetic mean
median() # median
      # standard deviation
sd()
table() # shows frequencies of factor/category variables
var(x) # (sample) variance
guantile() # guantile
min() # minimum value
max() # maximum value
range()
         # range with minimum and maximum value
# I recommend using these with sapply() command, for instance
sapply(my_data, mean, na.rm = T) # will procude mean for every
variable in mv data
```

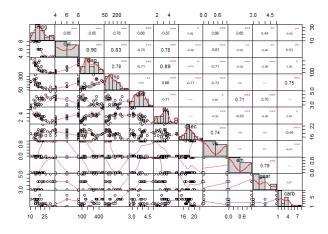

Key R Commands

```
• • •
# There are several packages out there for quick descriptive
library(psych)
describe(mtcars) # mtcars is a built-in data in R
```

```
sd median trimmed
                                            mad
                                                  min
                                                              range skew kurtosis
     vars n
              mean
                                                          max
                                                                                       se

```

Key R Commands: Correlation Matrix

```
. . .
library(PerformanceAnalytics)
```

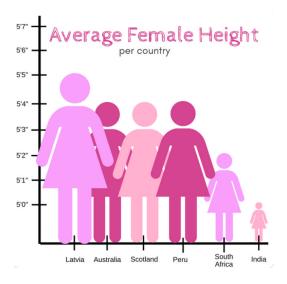

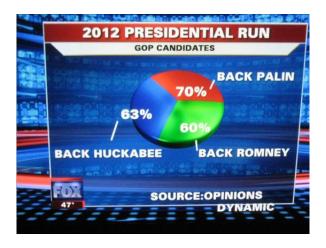

Why Graphs?

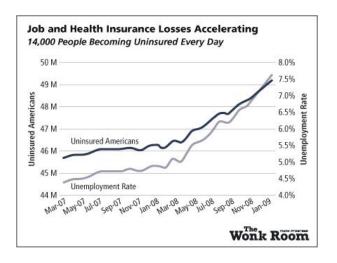

- Good Graphs:
 - Provide clear comparison
 - Are more intuitive to interpret than tables
 - Allow the reader to make an informed decision on the data
 - Can show confidence measures more intuitively than tables
- Graphs are always better than tables. However, if you have to make a table, here is a guide.

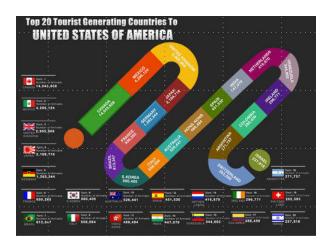

Common Graphing Problems Scaling

- Leaving out the baseline
 - Exaggerates difference between similar numbers
 - Downplays major differences
- Deceptive/meaningless sizes, shapes, and/or scales
- Unclear or poorly labeled axes
- Leaving out corrections (inflation, time, population growth, etc.)
- Deceptive selection of base years

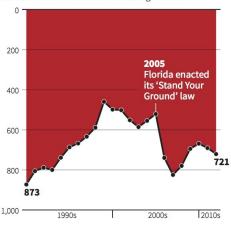

Gun deaths in Florida

Number of murders committed using firearms

Source: Florida Department of Law Enforcement

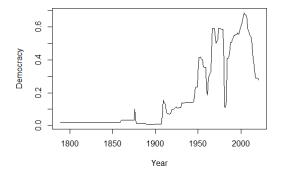

Common Graph Types for Descriptive Statistics

- Line Plots: good for showing changes over time
- Bar Plots: good for comparing discrete data or descriptives of different variables
- Histogram: similar to a bar plot, but for frequency distribution
- Box Plot: good for showing distribution of a variable
- Scatter Plot: useful for showing bivariate relationships

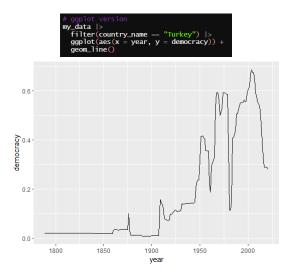

Common Graph Type Examples

 For these examples, we'll use Varieties of Democracy (V-Dem) dataset

Line Plot in Base R

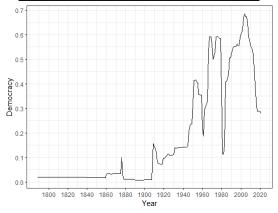

Line Plot in ggplot2

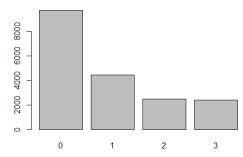

Line Plot in ggplot2, but publishable quality!

```
# Let's make it pretty
my_data |>
filter(country_name == "Turkey") |>
ggplot(aes(x = year, y = democracy)) +
geom_line() +
theme_bw() +
labs(x = "Year", y = "Democracy") +
scale_x_continuous(breaks = seq(1800, 2020, by = 20)) +
scale_y_continuous(breaks = seq(0, 1, by = 0.1))
```

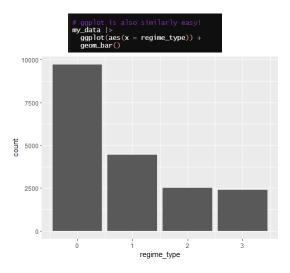

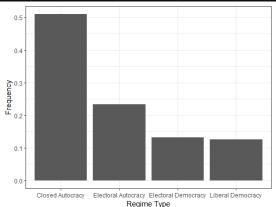

Bar Plot in Base R

```
str(my_data$regime_type)
plot(as.factor(my_data$regime_type))
```

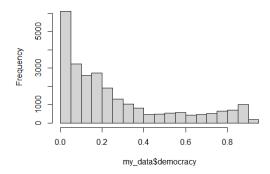

Bar Plot in ggplot2

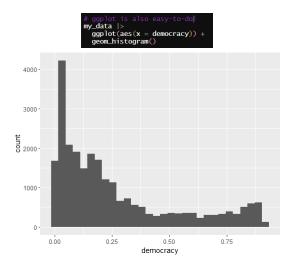

Histogram of my_data\$democracy

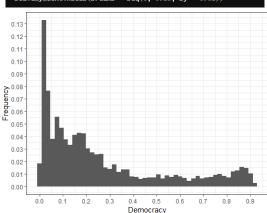

Histogram in ggplot2

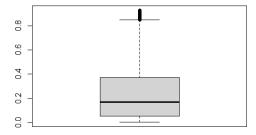

Histogram in ggplot2, but publishable quality!

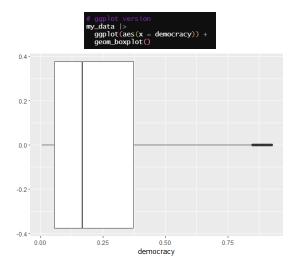

```
mv data ∣>
 ggplot(aes(x = democracy, y = (..count..)/sum(..count..))) +
 geom_histogram(bins = 50) +
labs(x = "Democracy", y = "Frequency") +
 theme bw() +
 scale_x_continuous(breaks = seq(0, 1, by = 0.1)) +
 scale_v_continuous(breaks = seq(0, 0.15, by = 0.01))
```

Box plot ---boxplot(my_data\$democracy)

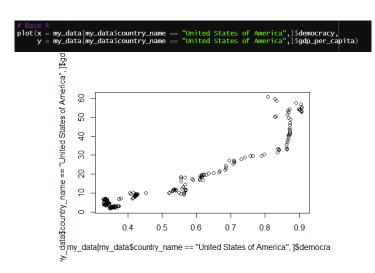

Box Plot in ggplot2

Box Plot in ggplot2, but publishable quality!

```
mv data |>
  qqplot(aes(x = factor(0), y = democracy)) +
  geom_boxplot() +
  labs(x = "Democracy", y = "") +
  theme bw() +
  theme(axis.text.x = element_blank(),
   axis.ticks.x = element_blank()) +
  scale_ycontinuous(limits = c(0, 1), breaks = seq(0, 1, by = 0.1))
